

## Introduction

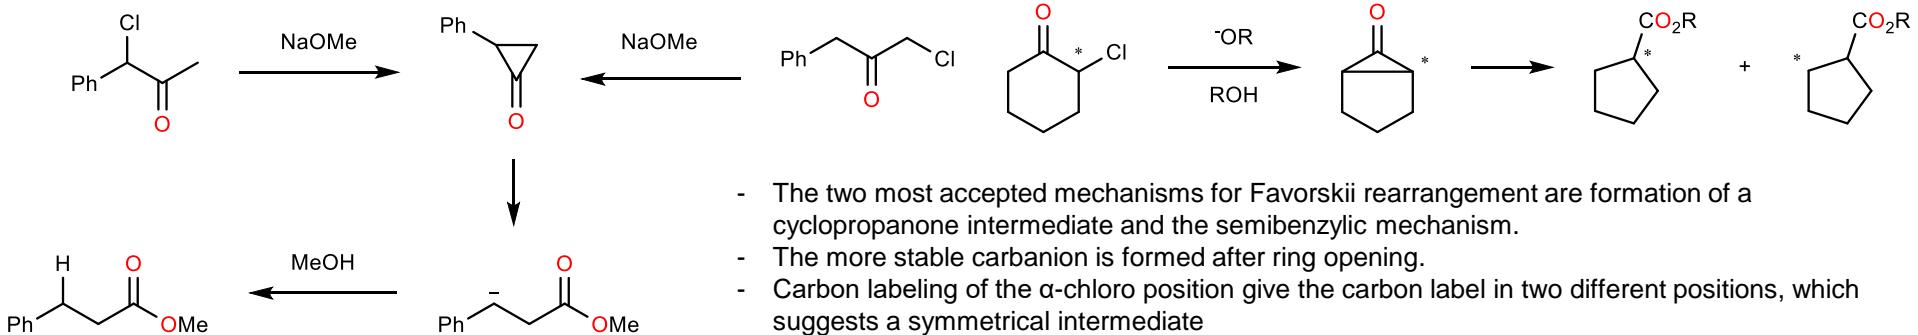

Alexei Favorskii

- First reported by Alexei Favorskii in 1892.
- Favorskii occurs with  $\alpha$ -halo ketones and proceeds via a cyclopropanone intermediate.
- Homo-Favorskii occurs with  $\beta$ -halo ketone and proceeds via a cyclobutanone intermediate.
- Quasi Favorskii occurs when no enolizable protons are present.

Favorskii, A. *Zh. Rus. Fiz.-Khim. O-va* **1892**, 24, 254.

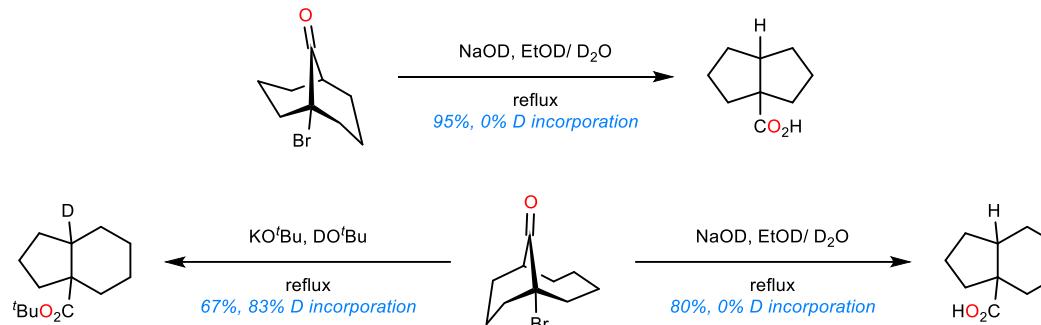

## Mechanism

- The two most accepted mechanisms for Favorskii rearrangement are formation of a cyclopropanone intermediate and the semibenzyllic mechanism.
- The more stable carbanion is formed after ring opening.
- Carbon labeling of the  $\alpha$ -chloro position give the carbon label in two different positions, which suggests a symmetrical intermediate

## Quasi-Favorskii vs Favorskii

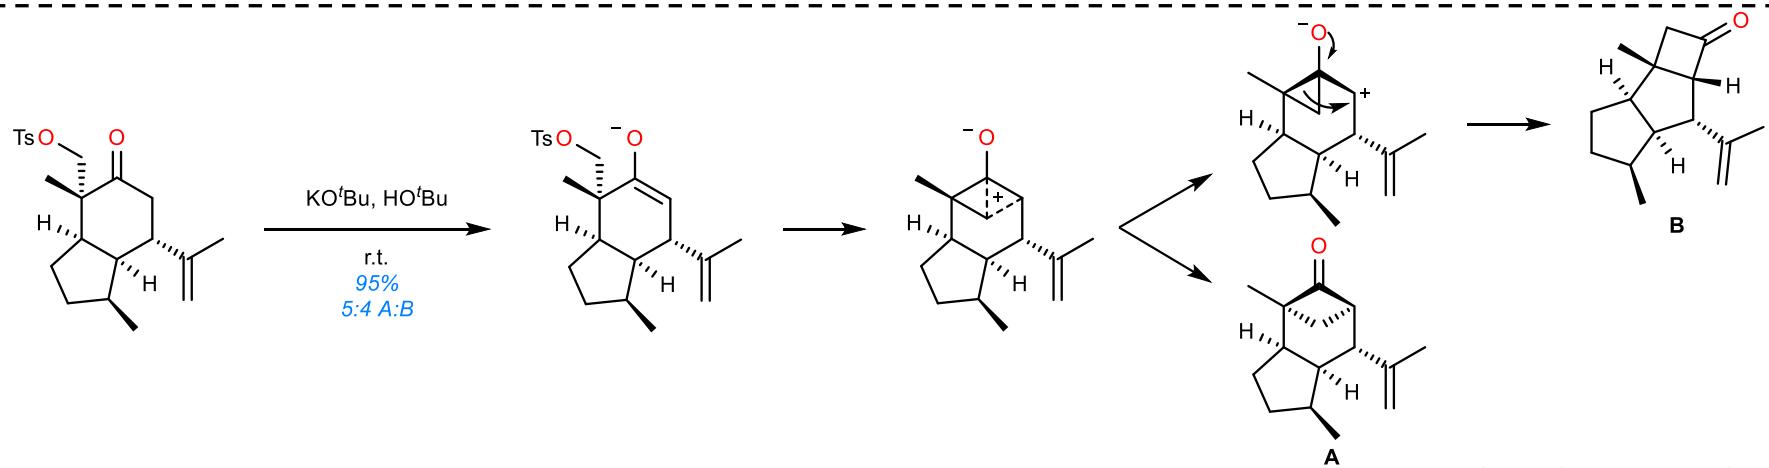

- Quasi-Favorskii proceeds by a semi-benzylic mechanism.
- Typically occurs when there are no enolizable protons or if the resulting cyclopropanone intermediate is too strained.
- No deuterium incorporation suggests a semi-benzylic mechanism.
- It is possible to switch between the cyclopropane and semi-benzylic mechanism by changing the conditions.
